Central Leather Research Institute, Madras

Market quality fallen and slaughtered hides collected from different centres are converted into full chrome shoe upper leather; the leather making potentiality of fallen hides is compared with that of slaughtered hides. The market quality fallen hides are found to be roughly of the same quality as the slaughtered hides. The qualities of finished leathers produced from slaughtered and fallen hides are comparable. The present investigation shows that the leather making property of fallen hides is dependent on their quality in the raw state and that there is no inherent difference between fallen and slaughtered hides arising simply out of the fact that the animal is fallen or slaughtered.

Introduction

In a previous study¹ on the comparative leather making property of slaughtered and fallen cattle hides, samples of fallen hides were collected at random from the Flaying and Carcass Utilisation Centres and the slaughtered hides from slaughter houses. A good portion of such fallen hides was found to be poorer in quality than the corresponding slaughtered hides. Such deterioration in quality was due to microbial action on account of prolonged delay in flaying and curing, inadequate cure and careless handling. In India, fallen and slaughtered hides are graded according to their qualities; hides of the same quality

are mixed together and then marketed. Slaughtered hides available in hide markets are not always obtained from organised slaughter houses but also from private butchers in the countryside. Hence it was considered worthwhile to verify and compare the leather making properties of market quality fallen hides with those of market quality slaughtered hides.

Materials and methods

Twelve slaughtered and twelve fallen cattle hides were collected from hide markets in Agra, Meerut and Jullundur in Northern India; twentyfour slaughtered and twentyfour fallen hides were obtained from raw hide dealers in Coimbatore, Bangalore and Ernakulam in Southern India.

* Forms part of J. K. K's thesis submitted to the University of Madras in partial fulfilment of the requirements for the M.Sc. degree.

Visual and histological assessment of the hides was made according to the methods reported earlier.¹ Tensile strength and elongation of the hides were determined after dehydration with acetone. Hides and finished leathers were analysed for (i) moisture, ash, fat and hydroxyproline and (ii) moisture, chromium oxide, fat and hide substance respectively as done earlier.¹ The procedure for grading the finished leathers and physical testing of the leathers has also been reported in the previous work.¹

Results

Visual assessment of the quality of slaughtered and fallen hides is given in Table 1. The qualities of slaughtered and fallen hides collected from different places in Northern and Southern India, as assessed by visual inspection, are comparable to each other without any great variation. The average classification of the total number of hides collected from the northern and southern regions is presented in Fig. 1.

FIG. 1. Visual assessment of the qualities of slaughtered and fallen hides as well as finished leathers

Classification of the hides as assessed by histological study is given in Table 2. This again shows that there is practically no variation in quality between the market quality slaughtered and fallen hides.

Tensile strength and elongation of the acetone dried hides are given in Table 3. The tensile strength of acetone dried samples of market quality fallen hides is comparable to that of market quality slaughtered hides. Elongation, however, appears to be higher in fallen hides than in slaughtered hides. On the other hand, strength-elongation product is found to be higher in fallen hides from northern and southern regions.

The data on chemical analysis of the slaughtered and fallen hides are presented in Table 4 which shows that chemical composition of the fallen hides collected from different hide markets does not vary to any appreciable extent from that of market quality slaughtered hides. This is quite probable in view of the fact that the fallen hides that are generally brought to the hide market are collected in time, cured in a better way and resalted, if necessary.

It is apparent from Table 5 that the qualities of the finished leathers obtained from market quality fallen hides are very well comparable to those of market quality slaughtered hides. Classification

| | Average of 24 hides | 39.0 | 15.5 | 3.80 | 10.5 |

of the total number of leathers from slaughtered and fallen hides based on their qualities is presented in Fig. 1.

The physical properties of the leathers made from slaughtered and fallen hides are presented in Table 6. Though there may be considerable variations between the maximum and minimum values both in case of slaughtered and fallen hides, the average values for tensile strength, elongation, stitch tear strength, tongue tear strength, grain cracking strength and bursting strength of leathers obtained from market quality fallen hides do not differ to any considerable extent from the corresponding average values of leathers from market quality slaughtered hides (Table 6). Average values

for strength-elongation product also appear to be close to each other.

Chemical analysis of the leathers produced from slaughtered and fallen hides is given in Table 7. Chemical composition of the leathers obtained from slaughtered and fallen hides appears to be practically identical.

Discussion

The leather making potentiality of market quality fallen hides collected from Northern and Southern India has been ascertained and compared with that of the market quality slaughtered hides. It is quite apparent from the visual and histological assessment of the raw hides that fallen hides are comparable to the slaughtered hides in raw quality. The average tensile strength being roughly

identical, the percent elongation appears to be slightly higher in acetone dried fallen hides. Chemical analysis of the hides also does not reveal any significant difference between the fallen and slaughtered hides.

Visual assessment of the finished leathers indicates that leathers produced from market quality fallen hides compare quite well with the leathers from slaughtered hides. Physical properties and chemical composition of the leathers also support this observation. The present investigation thus supports the view expressed in the previous study¹ that the leather making potentiality of fallen hides depends on their raw quality i.e., if the qualities of the fallen raw hides are comparable to those of slaughtered raw hides, their leather making potentialities are also comparable and that there is no in-

| | { Average | 15.0 | 4.08 | 3.78 | 64.5 |

herent difference between the two types of hides arising out of the animals being slaughtered or dying due to other causes. It has already been pointed out that fallen hides are often sold in Indian market according to their quality and so very poor quality hides are not generally brought to the market and hence the better quality fallen hides are obtained from the market.

Acknowledgment

This investigation is aided by a research grant (PL 480) from the United States Department of Agriculture.
